I. INTRODUCTION

In the mid to late 1970's, river sediments containing polychlorinated biphenyls (PCBs) were dredged from the upper Hudson River in the Fort Edward area and placed in several disposal sites in the vicinity. Two such sites, Special Area 13 and Bouy 212, are the subject of this report.

Special Area 13 (SA-13) and Bouy 212 (B-212), owned and maintained by the New York State Department of Transportation (NYSDOT), are located on the banks of the Hudson River. They were last used to store dredging spoils in 1979, at which time they were capped with 12 inches of topsoil and seeded. Yearly contracts are let by NYSDOT to maintain the turf cover and mow the grass.

Groundwater monitoring wells were installed at the two sites in 1979. Their purpose was to allow water samples to be extracted and tested for PCB concentrations, thereby gauging PCB levels leaching from the sites into the groundwater. These wells were subsequently replaced between 1981 and 1984, reportedly because they dried or experienced turbidity.

The existing monitoring wells are located both upgradient and downgradient of each site. Since 1980, groundwater samples from the wells have been tested an average of about four times per year. PCB concentrations have ranged from non-detectable to 66 parts per billion (ppb).

The U.S. Environmental Protection Agency (EPA) has suggested that water samples taken from the monitoring wells at disposal sites SA-13 and B-212 may not represent the actual concentration of PCBs leaching into the groundwater, and that additional wells may be needed. The reasoning being that the wells may not be located at the depths which contain the highest PCB levels. Because PCBs are "sinkers" (heavier than water), they could theoretically be descending through granular soil, where the wells are currently located, down to a layer of relatively impervious soil. Once the PCBs encounter this layer, they might concentrate at the surface of the layer, or migrate either in the direction of groundwater flow or in the direction of the downward slope of the impervious soil.

In April, 1990, a soils exploration program was instituted at SA-13 and B-212 to determine the elevation of impervious soil. Malcolm-Pernie Inc. (MPI) acted as Project Consultant and decided where the borings would be located. A representative from EPA was present during the drilling operations to determine the depth to which the borings would be progressed. Empire Soils Investigations performed the boring and sampling operations. Engineers and geologists from the New York State Department of Transportation Soil Mechanics Bureau (SMB) were present to collect soil samples and record visual descriptions of the soil encountered.

Using the data obtained from the boring program, as well as information from the existing wells, the Soil Mechanics Bureau generated subsurface profiles of the two sites. These profiles, included in Appendix A, identify the locations of the impervious soil strata. Hydrogeologic evaluations of the disposal sites, and recommendations concerning additional monitoring wells are presented herein.

II. LOCATION OF SITES

The Hudson River dredge disposal sites, Special Area 13 (SA-13) and Bouy 212 (B-212), are located in the Hudson-Champlain Lowlands Physiographic Province in New York State. Both sites are on the banks of the Hudson River within the river's flood plain: Site SA-13 is on the west bank in the Town of Moreau, Saratoga County, and Site B-212 is on the east bank in the Town of Fort Edward, Washington County. Both areas are approximately 45 miles north of Albany, NY.

III. GEOLOGIC HISTORY OF SOIL DEPOSITION IN THE AREA

In the waning years of the Pleistocene Epoch (Ice Age), the retreating Hudson Ice Lobe of the Wisconsin glacial advance supplied water to ice-marginal Lakes Albany and Quaker Springs. Melting soil-laden ice contributed a large sediment volume to the lake bottom, and a characteristic lacustrine sequence was deposited.

A bottom layer of interbedded gravel and sand underlies the stratified clay and silt lacustrines. Over these layers are deltaic silt and sand beds, which were deposited in shallow-water portions of the lake basin. Major tributaries transported large sediment volumes, and significant deltas were formed.

Further recession of the glacier, and an accompanying drop in water level, led to the transition from Lake Quaker Springs to Lake Coveville. Sediment contribution to this lake in the Hudson Lowland was limited to the pebble gravel, sand and silt transported by tributary streams.

In the latter stages of deglaciation drainage through this area, three separate water levels were formed, known as the Fort Ann Channels. They are considered a broad shallow river, 10 to 20 feet deep, with a significant south-flowing current capable of eroding the soft lacustrine bottom sediment and transporting sand. Tributary streams deposited fluvial-lacustrine sand where they joined the Fort Ann waters, and the prevailing current transported this sand southward, depositing it on eroded clay terraces and till/bedrock surfaces.

Ordovician sandstone and shale bedrock underlie this area.

Disposal sites SA-13 and B-212 exhibit generally similar stratigraphy. Soil borings at these sites substantiate the depositional process described above. The borings show that silts, sands and gravels from the Lake Coveville and Fort Ann events overlie layered silt and clay and silty clay deposits of the Lake Quaker Springs event. The following section of this report contains more detailed descriptions of the subsurface soil profiles for each site.

IV. SOIL AND HYDROGEOLOGIC CONDITIONS AT DISPOSAL SITES

A. SITE BOUY 212 (B-212)

1. General Soil Conditions

The general soil conditions at this site were determined through the interpretation of subsurface exploration logs and visual examination of soil samples from bore holes D-1, D-2, DNX-5 and DNX-6. These conditions are listed in Table 1, and shown on Drawing No. 1-SM-2320-D, "Bouy 212 General Subsurface Profile" in Appendix A.

2. **Hydrogeology** - Based on groundwater elevations taken in the borings and monitoring wells at this site, the phreatic surface slopes downward to the south in the direction of river flow, and west toward the Hudson River.

Soil strata containing clay occur at two distinct locations. The upper layer was found in the North at Elevation 118.5 and slopes down to the south to Elevation 99.5. At the northeast corner of the site, this layer is divided by a five feet thick deposit of silt and sand.

The lower clay-bearing stratum slopes from the North at Elevation 91 to the South at Elevation 89 (Appendix A, Drawing No. 1-SM-2320-D, Section A-A). This layer also slopes down to the west, toward the river.

Based on other subsurface explorations completed in this area (Fort Edwards Bridge over the Canal, and Special Area 13), it may be reasonable to assume that the lower clay-bearing layer is continuous. There is, however, a degree of uncertainty as to the continuity of the upper clay layer.

- In summary, the groundwater flow characteristics at this site tend to be toward the south and west during normal and low river levels. Groundwater recharge from the river may occur occasionally for short time intervals when the river level is high.

B. SITE SPECIAL AREA 13 (SA-13)

1. General Soil Conditions

The general soil conditions at this site were determined through the interpretation of subsurface exploration logs and visual examination of soil samples from bore holes C-1 through C-4, and DNX-1 through DNX-4. These conditions are listed in Table 2, and shown on Drawings Nos. 1-SM-2320-E and 1-SM-2320-F in Appendix A.

2. **Hydrogeology** - Based on the groundwater elevations recorded in the borings and monitoring wells at this site, the phreatic surface slopes gently southeast towards the Hudson River. Parallel to the river, the groundwater surface dips very gently south-southwest, in the direction of river flow.

TABLE 1
BORING LOG SUMMARY
SITE B-212

LAYER THICKNESS* (feet)	RANGE OF ELEVATIONS* (feet)	COMPACTNESS OR CONSISTENCY	SOIL DESCRIPTION
11-18	131-112	Very Loose to Medium Compact	Brown and Black Sandy SILT and Silty fine SAND
2-12	120-100	Very Loose to Medium Compact	Gray, Brown and Black Gravelly SAND to Silty SAND, Gravelly
1-15**	118.5-98.5	Very Soft to Soft	Layered: Gray and Gray/Brown Silty CLAY Clayey SILT fine Sandy SILT
10-13	104-89	Very Loose to Medium Compact	Brown and Black Sandy SILT and Silty fine SAND
0-6	91-85	Very Soft to Soft	Layered: Gray and Gray/Brown Silty CLAY Clayey SILT fine Sandy SILT
6-7	89-79	Very Soft to Firm	Gray and Gray/Brown Clayey SILT and Silty CLAY

- LOWER LIMIT OF BORINGS -

* LAYER THICKNESS and RANGE OF ELEVATIONS are based on multiple borings.

LAYER THICKNESS represents the minimum and maximum thickness of a soil deposit recovered from the borings at the site.

RANGE OF ELEVATIONS represents the highest elevation at which the top of a soil deposit was encountered, and the lowest elevation at which the bottom of a soil deposit was encountered, from the borings at the site.

** At northeast corner of site, five feet of Sandy SILT and Silty fine SAND was found within the layered CLAY and SILT described above.

The top of the clay-bearing strata was found to drop from Elevation 108 at the northeastern (upstream) end of the site, to Elevation 92 at the southwestern (downstream) end of the site.

The groundwater flow characteristics at this site appear to be south-east toward the river , and south-southwest in the direction of river flow. This will occur during normal and low river stages. Groundwater recharge from the river may occur occasionally for short time periods when the river level is high.

TABLE 2

BORING LOG SUMMARY
SITE SA-13

LAYER THICKNESS* (feet)	RANGE OF ELEVATIONS* (feet)	COMPACTNESS OR CONSISTENCY	SOIL DESCRIPTION
24-36	133-92	Very Loose to Medium Compact	Gray, Brown and Black Sandy SILT Silty fine SAND Gravelly SAND Silty SAND, Gravelly
5-13	108-79	Very Soft to Soft	Layered: Gray and Gray Brown Silty CLAY Clayey SILT, and fine Sandy SILT
0-4.5	97-92.5	Very Soft to Firm	Gray and Gray/Brown Clayey SILT and Silty CLAY

- LOWER LIMIT OF BORINGS -

* LAYER THICKNESS and RANGE OF ELEVATIONS are based on multiple borings.

LAYER THICKNESS represents the minimum and maximum thickness of a soil deposit recovered from the borings at the site.

RANGE OF ELEVATIONS represents the highest elevation at which the top of a soil deposit was encountered, and the lowest elevation at which the bottom of a soil deposit was encountered, from the borings at the site.

V. DISCUSSION OF EXISTING WELLS

Late in 1979, a total of six wells were installed at the two dredge disposal sites: DNX-5 and DNX-6 at Site B-212, and DNX-1 thru DNX-4 at Site SA-13 (see Appendix A, Drawing Nos. 1-SM-2320-A, B and C). They were to be used to monitor PCB concentrations in the groundwater around the perimeter of the sites. Personnel from New York State Department of Environmental Conservation (NYSDEC) and NYSDOT determined the location of the wells.

Soil samples were collected while progressing the borings, and Subsurface Exploration Logs were prepared for each hole. These logs are included in Appendix B.

A three inch inside diameter slotted plastic pipe was installed in each well, five feet below the recorded groundwater elevation. The depths of wells and water levels at the time of installation were as follows:

TABLE 3

ORIGINAL WELLS: DEPTHS AND GROUNDWATER ELEVATIONS

Site	Well No.	Ground Elevation (ft.)	Depth of Well (ft.)	Depth to Groundwater (ft.)
SA-13	DNX-1	121.4	6	1
SA-13	DNX-2	124.7	9	4
SA-13	DNX-3	121.9	10	5
SA-13	DNX-4	128.9	7	2
B-212	DNX-5	127.9	8	3
B-212	DNX-6	121.8	7	2

Around the end of 1980, DNX-4 and DNX-5 went dry. Over the next two years, problems such as high turbidity affected the other wells. By February, 1984, all six wells were replaced.

The replacement wells were installed close to the original well locations. Although correspondence indicates that Subsurface Exploration Logs for the new wells were transmitted to the appropriate offices, no such logs can be located.

The depths of the replacement wells, and their respective groundwater elevations, were measured on May 1, 1990. The data was recorded as follows:

TABLE 4

REPLACEMENT WELLS: DEPTHS AND GROUNDWATER ELEVATIONS

Site	Well No.	Ground Elevation (ft.)	Depth of Well (ft.)	Depth to Groundwater (ft.)
SA-13	R-1	121.3	10.15	0.70
SA-13	R-2	125.3	10.66	4.36
SA-13	R-3	121.7	11.55	0.92
SA-13	R-4	125.3	18.71	2.35
B-212	R-5	131.1	18.85	7.40
B-212	R-6	122.4	11.60	1.85

NYSDEC had conducted inspections and monitoring surveys at both sites from October 1, 1980 through March 31, 1989. Since then, NYSDOT has assumed responsibility for the laboratory analysis of samples taken from the wells. NYSDEC continues to perform sample collection, with the assistance of personnel from NYSDOT. The wells have been monitored an average of four times annually.

(See "History of Monitoring Wells" in Appendix C for a brief chronology of events concerning the existing wells, based on correspondence found in the Soil Mechanics Bureau files).

VI. CONCLUSIONS

Based on information obtained through the boring program, as well as from other sources (listed in Appendix E, Bibliography) the following conclusions have been made:

- Disposal sites B-212 and SA-13 are located on the Hudson River flood plain. They are underlain by lacustrine and recent alluvial deposits.
- The boring program confirmed the geologic history of soil deposition at each site.
- Both disposal sites are located on a relatively thick (30-40 feet) deposit of pervious granular soil, consisting of various combinations of sands, silts and gravels.
- A continuous confining soil layer exists 30-40 feet below each site. This impermeable clay layer dips to the south and towards the river at both sites.
- The groundwater surface at each site also slopes down toward the river and dips to the south.
- The existing monitoring wells are located in the upper layer of granular soil at each site. These are suitable to monitor floating contaminants.
- The existing monitoring wells are located upgradient and downgradient of each site.
- The separation of the upgradient wells from the mass of disposed, PCB-laden material may be insufficient to prevent contamination from the spoil areas.
- There may not be a sufficient number of downgradient wells at Site B-212 to accurately monitor PCB contamination from the disposal site, based on guidelines set forth in the EPA manual entitled "RCRA Ground-Water Monitoring Technical Enforcement Guidance Document".
- Because PCB's are "sinkers" (heavier than water), they will tend to descend through the groundwater, if the soil medium is of a porous nature, until their path is obstructed, such as by a less pervious confining layer. The PCBs will then concentrate at the surface of the confining layer, or migrate in the direction of ground water flow.

The present wells at disposal sites SA-13 and B-212 (Well Nos. R-1 thru R-6) are located in the upper soil layers of sand, silt and gravel. The bottoms of these wells are substantially above the continuous confining layers of clayey silt and silty clay. Based on the above discussion, it is possible that water samples extracted from these wells do not represent the actual PCB concentration leaching from the spoil areas.

To verify this, it will be necessary to install additional wells which extend to the top of the confining layers.

VII. RECOMMENDATIONS

As previously stated, deeper wells will be required in order to monitor PCB concentrations at the surface of the confining layers below both disposal sites SA-13 and B-212. Also, additional wells should be installed downgradient at Site B-212, to meet the requirements in "RCRA Ground-water Monitoring Technical Enforcement Guidance Document". All wells at Site B-212 should be of the cluster type, so groundwater can be monitored at the upper and lower confining layers.

A. WELL LOCATIONS AND ELEVATIONS

Presented below are this Bureau's recommended monitoring well locations and estimated screen elevations for each site:

Site	Station	Offset	Surface Elev.	*Estimated Screen Elevation (Bottom)	Screen Length (Feet)	Remarks
B-212	1+20	0	129.7	99	10'	Downgradient
B-212	1+20	0	129.7	88	10'	Cluster
B-212	7+00	120' Lt.	125.0	103	10'	Downgradient
B-212	7+00	120' Lt.	125.0	88	10'	Cluster
B-212	5+00	150' Rt.	125.0	104	10'	Upgradient
B-212	5+00	150' Rt.	125.0	88	10'	Cluster
SA-13	0+00	100' Rt.	122.0	90	10'	Downgradient
SA-13	5+60	100' Rt.	125.0	97	10'	Downgradient
SA-13	14+70	100' Rt.	121.0	97	10'	Downgradient
SA-13	7+30	300' Lt.	126.6	99	10'	Upgradient

*Actual elevations will be dependent upon soils encountered during drilling operations.

Note: The recommended well locations and depths are depicted on Drawings Nos. 1-SM-2320-A thru 1-SM-2320-F in Appendix A.

B. CONSTRUCTION OF WELLS

1. Drilling Method

We recommend that six-inch inside diameter casing (size designation SW) be driven, with a split spoon sampler continuously advancing the hole the last ten feet to obtain an accurate measurement of the soil stratigraphy. This is important in determining the exact elevations of the confining layer(s).

All drill rods and casings should be steamed-cleaned so contaminants cannot be introduced into the boreholes. The water supply should be obtained from a municipal source, and not the river, to preclude the possibility of using PCB contaminated water.

2. Well Casing and Well Screen

We recommend Threaded Flush Joint PVC with an inside diameter of two inches. Well screens should be 10 feet in length and be sand packed.

These wells can be constructed inside the six inch diameter drill casing. Figure 1 shows a typical cross section of a monitoring well.

3. General

During construction of these wells, it is important that very careful measurements be taken while advancing the boreholes, and that the samples be examined closely to accurately determine the elevation of the confining layer.

The well screens should be embedded six inches to one foot into the confining layer. This will be critical at Site B-212 when installing wells in the upper confining layer, which is very thin at one location.

APPENDIX C
HISTORY OF EXISTING MONITORING WELLS

APPENDIX C

HISTORY OF EXISTING MONITORING WELLS

The following outline is a brief chronology of events concerning the installation and subsequent replacement of six monitoring wells at the subject sites. In many cases statements from correspondence are quoted verbatim. In other cases, only general information from certain correspondence is included.

- A Malcolm Pirnie Interim Report to Mr. Eldred Rich of the NYS Department of Conservation (NYSDEC) dated August 25, 1975, recommends the installation and periodic sampling of observation wells at the spoil sites. It says that the "locations and characteristics of the ... wells will be governed by the specific hydrogeologic conditions at the spoil sites." These wells would be used to monitor PCB levels at the spoil sites.
- November 7, 1979 memorandum from the New York State Department of Transportation (NYSDOT) Soil Mechanics Bureau (SMB) to Region 1 Director C. Carlson, requesting that six wells be installed at the sites: four at Special Area 13 (SA-13) and two at Bouy 212 (B-212). The memo states, "The wells should consist of 3 inch inside diameter slotted plastic pipe ... progressed to a depth of 5 feet below water table ... It is anticipated that the wells will average 10 feet in depth." SMB requested that these wells be installed prior to December 14, 1979. The memo also states that representatives from NYSDEC, SMB and the NYSDOT Waterways Maintenance Division (WMD) should locate the wells.
- From November 30, 1979, to December 24, 1979, borings DNX-1 thru DNX-6 were progressed at the two sites. The logs indicate the depth to water was from one foot (DNX-1) to five feet (DNX-3) below original ground surface, and that a three inch slotted plastic pipe was progressed five feet below the indicated depth to water. The slotted pipe was also one foot above the bottom of the hole (as per typical groundwater monitoring well section).
- January 14, 1981 memorandum from SMB to WMD noting that SMB has reviewed difficulties encountered in Observation Wells 4 and 5 with Dr. Tofflemire of NYSDEC and, in order to meet his (Dr. Tofflemire's) requirements, it will be necessary to install wells which will be sand-packed well point systems. Two inch inside diameter flush thread joint pipe (Schedule 80) was ordered: two five foot screens, eight five foot solid pipes and two threaded caps.
- January 20, 1981 memorandum from SMB to C. Carlson requesting Wells 4 and 5 be replaced. NYSDEC has requested these be replaced in order to provide the necessary sampling as required by the United States Environmental Protection Agency (EPA) monitoring orders for these disposal sites.

The memo reads, "We request that these be progressed to a depth of 20 feet and be of the sand packed well point type. The necessary supplies have been requested from the Waterways Maintenance Division ...".
- April 27, 1981 memorandum from Dr. Tofflemire (NYSDEC) to Mr. Stellato (WMD Director) which reads, "I understand NYSDOT will be installing new

wells ... because these wells were dry. It is also requested that ... No. 3 at SA-13 site be replaced because of high turbidity in the water".

- May 7, 1981 handwritten note to JR (assumed to be John Rumsey, NYSDOT Region 1 Soils Engineer) from an unknown source (signature is illegible) reads "As per W. Schollenburg (assumed to be William Schollenberger, WMD Engineer) - #3 well replacement was deleted until results of #4 and #5 are received.

"Well point not needed -

Encon (NYSDEC) and Waterways (WMD) decided this but did not let us (SMB) know."

- September 3, 1982 memorandum from WMD to D. Geoffroy, NYSDOT Region 1 Director, states that in 1981 Regional forces replaced wells Nos. 4 and 5, and that NYSDEC is now requesting wells Nos. 2, 3 and 6 also be replaced.
- September 28, 1982 memorandum from WMD to Geoffroy states that the EPA requires that well No. 1 also be reconstructed, and requests NYSDOT Region 1 personnel to do the work.
- October 25, 1982 memorandum from J.P. Rumsey, Region 1 Soils Engineer to WMD, ordering 60 linear feet of six inch casing to replace wells Nos. 1, 2, 3 and 6. This memo states that "We will only install the outer shell of the observation wells."
- January 26, 1984 message from Geoffroy to Rumsey asking if the installation of EPA monitoring well (unspecified) was done yet. Rumsey replied that the installation of the wells was completed on February 6, 1984.
- Undated memorandum from Rumsey to SMB stating that copies of logs of Drill Holes 4R & 5R are transmitted herewith (no logs found in 1990).
- Undated memorandum from Rumsey to WMD stating that copies of logs of Drill Holes DNW 1R, 2R, 3R, and 6R are transmitted herewith (no logs found in 1990).

Note: Upstream well #4 was replaced in 1991. Well #4 was progressed to a depth of 20' and sand packed.
 Downstream well #'s 1-3 were replaced in February 1994.
 They were progressed to depths of 9.5', 11', and 12' respectively and sand packed.
